Flouride rich baby food under fire from scientists

Daniel Zimmermann

NEW YORK, USA/LEIPZIG, Germany: Scientists in the US have warned of the risks of exposing young children to large amounts of fluoride. In a study published in the October edition of the Journal of the American Dental Association they claim that an increased intake of the mineral from drinking water, dentifrice, infant powder products or beverages can lead to a higher risk of developing fluorosis, a condition that discolours and weakens teeth.

The findings confirm earlier evidence indicating a link between dental fluorosis and greater intake of fluoride in early life. The latest study, conducted by researchers from the University of Iowa in the United States, found that a greater fluoride intake from reconstituted powder, a popular choice for infant food in the US, and other beverages with added water increased fluorosis risk in children between the ages of three and nine months. They suggested avoiding the ingestion of additional fluoride through consumption of these mixtures in order to reduce the prevalence of the condition nationwide.

New evidence links mercury to Alzheimer’s

Yvonne Bachmann

LEIPZIG, Germany: Dental patients with silver fillings are more likely to suffer from senile dementia of the Alzheimer’s type. In a review published in the latest Journal of Alzheimer’s Disease, researchers associated with universities in Boston (USA), Freiburg/Berlag and Frankfurt (Oder), both in Germany, claim that symptoms of the condition were reproduced or accelerated when brain tissue was exposed to inorganic mercury, the main ingredient of amalgam.

Earlier studies of low-dose human exposure, such as to dental patients and their staff, have shown that exposure to mercury is correlated with long-term neurological or psychological harm. The new review is one of the first that has found a systematic link between mercury and increased levels of mercury found in Alzheimer’s patients.

According to Prof. Harald Walach, Viadrina European University in Frankfurt (Oder), patients with silver fillings are exposed to 1 to 22 µg mercury per day, of which the majority accumulates in the brain. The metal binds with selenium, a substance responsible for preventing oxidative stress, which can lead to cell death and early ageing. Removing mercury from medical and ecological cycles could slow down cell death and prevent the development of dementia and possibly other forms of neurological disorders, including Parkinson, he added. “The situation is similar to the early 1970s regarding smoking: substantial experimental evidence existed, but human studies were inconclusive at the time and were under attack by groups with a vested interest,” Prof. Walach told Dental Tribune Asia Pacific. “To wait until irrefutable evidence has accumulated is not the best option in view of what we already know about the toxic potential of mercury.”

Amalgam is still the most common type of filling used by dentists worldwide. It is banned in Sweden and restricted in Norway and Denmark. (Edited by Daniel Zimmermann, DTT)
Prison dentist gets prison sentence

A dentist who treated jail inmates has been given a 2.5-year prison sentence for defrauding the NHS.

According to news reports, John Hudson was jailed for claiming more than £500,000 from the health service by billing twice for the same treatment.

Hudson, 58, provided dental care for inmates at HMP Altcourse, a privately run facility at Fazakerley near Liverpool. Dental services at Altcourse were also contracted out and the dentist took advantage of a change in NHS accounting and billing systems in 2006.

The court heard that a good part of the illegally gotten payments went on fees for the education of his three children and holidays, but he now owes £40,000 and is being sued by the NHS for £500,000.

Hudson admitted to two charges of dishonesty and illegally obtaining credit from the health service. Judge Graham Morrow QC, who sentenced Hudson yesterday at Liverpool Crown Court, said that Hudson had held a respected position in the community at the nearby town of Whitworth, but had committed acts of blatant dishonesty that deprived patients of money that should have gone towards their care.

It was revealed that Hudson was paid by HMP Altcourse but also claimed £507,000 over two years.

It was also reported that Hudson approached Liverpool Primary Care Trust about a contract at the jail demanding £247,000 a year; he went on to accept half that figure.

EAO votes first Brit for president

Daniel Zimmermann

LONDON, UK/LEIPZIG, Germany: Dr David A. Stone has been elected the first British President of the European Association for Osseointegration (EAO). The dentist from Perthshire in the UK, who also serves as Chairman of the Royal College of Surgeons of Edinburgh Advisory Board in Implant Dentistry, took over from Prof. Christoph Hämmerle, Switzerland, during the association’s recent congress in Glasgow in October. He will serve as president for 2011/2012.

The meeting also saw Prof. Soren Schou from Denmark installed as President-Elect. French Prof. Pascal Valentini from Paris will be taking over as new Secretary-General.

“Dentistry is still an ‘empirical discipline’, relying on evidence to provide the most appropriate way of treating patients. A very important part of the EAO’s philosophy is to bridge the gap between science and clinical practice.” Dr Stone told Dental Tribune Asia Pacific. “As president of this organisation I intend to ensure that this is further strengthened in a way that is relevant to modern practice.”

Founded in Munich in Germany in the late 1980s, the EAO aims to promote and facilitate research, clinical applications, and treatment methods based on the principles of osseointegration.

The organisation’s recent congress in the UK focused on a wide range of surgical, prosthetic and planning processes in implant dentistry.

Malpractice in Pakistan spreads

Policy makers in Pakistan have urged the governments to condemn the spread of medical malpractice through tougher restrictions on the registration of medical and dental personnel. According to the Pakistan Ministry of Health, over 200,000 doctors including 70,000 dentists currently practice without a licence.

Korean kids have better oral health

Dentists from the Department of Preventative and Public Health Dentistry at the Seoul National University in South Korea have reported a decline of dental decay among children. Most improvement was observed in the age group 9 where, in 2006, over 40 per cent had lower caries levels compared to the year 2000.
A-dec Introduces Its Newest Family Member: A-dec 200™

New Point-of-entry A-dec 200 Offers No-Compromise Performance and Real A-dec Value

A-dec, a global leader in dental equipment, introduces A-dec 200™, the newest in A-dec’s lineup of patient chairs and delivery systems, with input from dental professionals around the world to accommodate the wide range of practice styles found in global markets.

The space-saving chair-mounted delivery system includes a telescoping assistant’s arm and an oversized tray to hold everything the dental team needs. The new multi-axis light provides easy and precise positioning of illumination, and the cuspidor rotates conveniently to the patient when needed. The chair, light and cuspidor functions are easily controlled from A-dec’s modern touchpad and small and large practices will enjoy the open platform that leaves room to add or change ancillary devices for peak performance now, and in the future.

To learn more about A-dec 200, contact your local authorized A-dec dealer. www.a-dec.com.

Colgate ranks top among Asian customers

Daniel Zimmermann

HONG KONG/LEIPZIG, Germany: Consumers in Singapore, Malaysia and Hong Kong consider Colgate one of their favourite brands. A recent survey conducted by the Nielsen Company Singapore & Malaysia has found that Colgate, a toothpaste manufactured and distributed by US-based consumer products giant Colgate-Palmolive, is a brand preferred by the majority of consumers in all three markets. A similar survey in India also put it amongst consumers’ most trusted brands.

Colgate has ranked top amongst consumers in recent years but has had to relinquish the top spot recently to other companies, including Nokia and Internet giant Google. However, the brand was the only one to achieve top ten rankings in all four countries, Nielsen reports.

Colgate, which is based in New York, is one of the largest distributors of consumer dental products worldwide. In 2009, the company reported a record profit of US$685 million, which they said was mainly driven by increasing toothpaste sales globally. Colgate also sells manual and electric toothbrushes, mouthwash, and tooth-whitening products.

“In this time of economic uncertainties, it is even more crucial to have strong brands to retain customer loyalty and sustain business growth. Brands with the greatest equity are more likely to tide over the tough times, as customers are willing to pay higher prices for products which they have established a closer relationship with,” said Paul Richmond, Managing Director, Consumer Group, the Nielsen Company Singapore and Malaysia.

The Nielsen reports identified over 500 brands across 93 categories of consumer products and services in Singapore, Malaysia, Hong Kong and India.

**Frenectomy review: comparison of conventional techniques with diode laser**

**Authors:** Dr M.L.V. Prabhuji, Prof Dr S.S. Madha Preetha, Dr Ameya G. Moghe, India

---

**Introduction**

The word frenum is derived from the Latin word “frænum”, French for a horses tongue-shaped folds found in the maxillary and mandibular alveolar mucosa, and also for the frenum in the central incisors and canine premolar area. Frenum may be classified depending upon the attachment level, frenum has been classified as:

- **Long and thin**
- **Short and broad**

Depending upon the attachment level, frenum may be classified as:

- **Macosal**
- **Gingival**
- **Papillary**
- **Papillary penetrating**

When the insertion point of the frenum is at the gingival margin it may pose a problem (Corn 1964). This kind of abnormal insertion of the frenum may cause marginal recession of the gingiva. Abnormal frenal insertion can distort and retract the marginal gingiva or pull away from the tooth when the lip is stretched. A frenum that encroaches on the margins of the gingiva may interfere with plaque removal, and tension on this frenum may tend to open the sulcus. This condition may be more conducive to plaque accumulation and thus motivate proper oral hygiene. Algicarent frenum can be treated by frenectomy or frenotomy procedure.

Frenectomy is carried out by incision and relocation of the frenum.

---

**Indications**

- The indications for frenectomy procedure include:
- Tension on the gingival margin (frenal-pull consonant with or without gingival recession)
- Facilitate orthodontic treatment
- Facilitate home care
- Conventional technique
- Using soft tissue lasers.

---

**Conventional technique**

Conventional technique utilises traditional instruments like the scalpels and periodontal knives. Different procedures have been mentioned under the conventional frenectomy technique. These include Dieffenbach, Schuchardt, and Mathis. The most common being Dieffenbach V-plasty & Schuchardt Z-plasty.

---

**Armamentarium**

Bard-Parker handles no. 5, No. 15 blade, mosquito haemostat, sutures and needle.

**Procedure**

Dieffenbach V-plasty

Surgical steps: The area is anesthetised by giving local anesthetic injection (2 % lignocaine with 1,200,000 adrenaline). After anesthesia is achieved, the frenum is held with mosquito haemostats to its full depth. With the No. 15 blade mounted on a Bard-Parker handle, an incision is made along the upper surface of the haemostat till the entire depth of the frenum extends as a V-shape. A similar incision is repeated on the under surface of the haemostat so that the haemostat is detached along with the frenum tissue within its breaks. Once this is achieved, a rhomboid area exposing the deeper connective tissue fibers becomes visible. With the help of fine scissors, the deeper fibers are detached from the underlying periodontium. Periosteal sounding is done with the help of surgical blade so as to prevent the reattachment of fibers. The labial mucosa is undermined so as to permit the approximation of the edges. The bleeding is controlled by applying pressure pack.

Sutting: The diamond shaped wound is sutured using either a 4-0 or 5-0 silk sutures in simple interrupted fashion. Proper approximation of the margins is ensured. A periodontal dressing is placed to cover the surgical area.

Frenectomy by V-plasty may result in scar formation that could prevent the mesial movement of the central incisors (West 1968). However, it is typically a safe surgical procedure with no notable complications.

---

**Carbon dioxide laser**

The carbon dioxide lasers have a wavelength of 10,600 nm. The beam of this laser falls in the infrared range and is thus invisible. This made the use of CO2 lasers awkward. Thus later on a quartz fiber incorporating a 650 nm coaxial He:Ne laser was used as an aiming beam in the handpiece. The CO2 laser received safety clearance from FDA in 1976 for use in soft tissue surgery. With the CO2 laser there is rapid intracellular rise of temperature and pressure leading to cellular rupture and release of ‘laser plume’ (vapour and cellular debris). The CO2 laser is readily absorbed by water. Soft tissue consists of 75 % to 90 % water, 98 % of the incident energy is converted into heat and absorbed at the tissue surface with very little scatter or penetration. Thus moist surface is essential for maximal effect. With CO2 laser no contact is made with the tissue, and no tactile feedback occurs.

---

**Nd:YAG laser**

The Nd:YAG laser has a wavelength of 1.064 µm and lies in the infrared zone like the CO2 laser. The Nd:YAG laser penetrates water up to 60 µm after which it is attenuated 10 % of its original strength. The Nd:YAG laser is absorbed in soft tissue rather than being absorbed onto the surface. The wavelength of Nd:YAG laser is associated to colours and as a result, its scattering in heavily pigmented soft tissues like skin is almost double its absorption.

This heating effect of the Nd:YAG laser is ideal for the ablation of superficial haemorrhagic abnormal tissue and for haemostasis of small capillaries and veins. In 1989, the FDA approved soft tissue removal by means of a pulsed Nd:YAG laser. In 1997, the FDA approved pulsed Nd:YAG laser is an Nd:YAG laser.

---

**Erbium:YAG laser**

The Er:YAG laser was introduced in 1974 by Zabihov et al. as a solid-state laser that generates a light with a wavelength of 2.940 nm. Of all lasers emitting in the near- and mid-infrared spectral range, the absorption of the Er:YAG laser in water is the greatest because its 2.940 nm wavelength coincides with the large absorption band for water.

The absorption coefficient of water of the Er:YAG laser is theoretically 10,000 and 15,000times higher than that of the CO2 and the Nd:YAG lasers, respectively. Since the Er:YAG laser is well absorbed by all biological tissues that contain water molecules, this laser is indicated not only for the treatment of soft tissues but also for ablation of hard tissues. The FDA approved the pulsed Er:YAG laser for hard tissue treatment such as caries removal and cavity preparation in 1997, unchanged for soft tissue surgery and sulcular debridement in 1999 and for osseous surgery in 2004.
_Diode lasers_

The diode laser is a solid-state semiconductor laser that typically uses a combination of Gallium (Ga), Arsenide (As), and other elements such as Aluminum (Al) and Indium (In) to change electrical energy into light energy. The wavelength range is about 800–980 nm. The laser is stabilized in continuous wave and gated-pulsed modes, and usually operated in a contact method using a flexible fiber optic delivery system. Laser light at 800–980 nm is poorly absorbed in water, but highly absorbed in hemoglobin and other pigments (ALD 2000). Since the diode basically does not interact with dental hard tissues, the laser is an excellent soft tissue surgical laser (Romanos G, 1999), indicated for cutting and coagulating gingiva and oral mucosa, and for soft tissue curettage or surgical debridement.

The FDA approved oral soft tissue surgery in 1995 and sulcular debridement in 1998 for laser use in dentistry. The diode laser exhibits thermal effects using the “hot-tip” effect caused by heat accumulation at the end of the fiber, and produces a relatively thick coagulation layer on the treated surface (ALD 2000). The usage is quite similar to electrosurgery. Tissue penetration of a diode laser is less than that of the Nd:YAG laser, while the rate of heat generation is higher (Rastegar S 1992), resulting in deeper coagulation and more charring on the surface compared to the Nd:YAG laser. The width of the coagulation layer was reported to be in excess of 1.0 mm in an incision of bovine oral soft tissue in vitro (White JM 2002). The advantages of diode lasers are the smaller size of the units as well as the lower financial costs.

_Argon laser_

The argon laser uses argon ion gas as an active medium and is fiber optically delivered in continuous wave and gated pulsed modes. This laser has two wavelengths, 488 nm (blue) and 514 nm (blue-green), in the spectrum of visible light. The argon laser is poorly absorbed in water and therefore does not interact with dental hard tissues. However, it is well absorbed in pigmented tissues, including hemoglobin and melanin, and in pigmented bacteria.

The argon laser was approved by the FDA for oral soft tissue surgery and curing of composite materials in 1991 and for tooth whitening in 1995. Considering the advantages of eradication of pigmented bacteria, this laser may be useful for the treatment of periodontal pockets.

_Alexandrite laser_

The Alexandrite laser is a solid-state laser employing a gemstone called Alexandrite, which is chromium-doped: Beryllium-Aluminum-Oxide (BeAl2O4) and is one of the few trichroic minerals. Rechmann & Henning first reported that the frequency-doubled Alexandrite laser (wavelength 532 nm, pulse duration 100 ns, double spikes, q-switched) could remove dental calculus in a completely selective mode without ablating the underlying enamel or cementum. The development of this laser for clinical use is widely expected due to its excellent ability for selective calculus removal from the tooth or root surface without ablating the tooth structure.

_Fracturemometry procedure using diode lasers Diode laser (A.R.C. Fox(3)) with wavelength of 810 nm was selected for the procedure. No local anesthesia was given to the patient. The frenum was stretched to visualize its extent. The diode laser was applied in a contact mode with focused beam for excision of the tissue. The ablated tissue was continuously mopped using wet gauze piece. This takes care of the charred tissue and prevents excessive thermal damage to underlying soft tissue. The tissue was lasered until all the underlying muscle fibers were dissected. No sutures were placed at the end of this procedure. Patients were asked to take analgesics only if needed. Advantages of Laser over Conventional technique: No need of local anesthesia. Hence it’s a painless procedure. As a result there is less patient apprehension. Bloodless operative field, thus better visibility. No need of periodontal dressing, therefore no patient discomfort.
Two-dimensional imaging modalities have been used in dentistry since the first intra-oral radiograph was taken in 1886. Significant progress in dental imaging techniques has since been made, including panoramic imaging and tomography, which enable reduced radiation and faster processing times. However, the imaging geometry has not changed with these common used intraoral and panoramic technologies.

 Cone-beam computed tomography (CBCT) is a new medical imaging technique that generates 3-D images at a lower cost and absorbed dose compared with conventional computed tomography (CT). This imaging technique is based on a cone-shaped X-ray beam centred on a technique is based on a cone-beam algorithm developed by Feldkamp et al. in 1984. Images of the craniofacial region are often collected with a higher resolution than those collected with a conventional CT. In addition, the new systems are more practical, as they come in smaller sizes.2 Today, much attention is focused on the clinical applications—diagnosis, treatment and follow-up—of CBCT in the various dental disciplines. The goal of the following systematic review is to review the available clinical and scientific literature pertaining to different clinical applications of CBCT in the dental practice.

Materials and methods

Clinical and scientific literature discussing CBCT imaging in dental clinical applications was reviewed. A MEDLINE (PubMed) search from 1 January 1994 to 15 July 2010 was conducted. Cone-beam computed tomography in dentistry was used as key phrase to extend the search to all the various dental disciplines. The search revealed 540 papers that were screened in detail. Owing to a lack of relevance to the subject, 405 papers were excluded. Thus, the systematic review consisted of 154 clinically relevant papers, which were analysed and categorised (Table 1).

Analysis

Oral and maxillofacial surgery

CBCT enables the analysis of jaw pathology,1,3 the assessment of impacted teeth (Fig. 1), super-numerary teeth and their relation to vital structures,2,2,4 changes in the cortical and trabecular bone related to bisphosphonate-associated osteonecrosis of the jaw2,2 and the assessment of bone grafts.2 It is also helpful in analysing and assessing paranasal sinuses4,5 and obstructive sleep apnea.2,7,8 As the images are collected from many different 2-D slices, the system has proven its superiority in overcoming superimpositions and calculating surface distances.6,8 This advantage made it the technique of choice in mid-slice fracture cases,29 orbital fracture assessment and management21 and for inter-operative visualisation of the facial bones after fracture.3,2,4,25 Since it is not a magnetic resonance technique, it is the best option for intra-operative navigation during procedures, including gun-shot wounds.2,28

CBCT is largely used in orthodontic surgery planning when facial orthomorphological surgery is indicated that requires detailed visualisation of the inter-occlusal relationship in order to augment the 3-D virtual skull model with a detailed dental surface. With the aid of advanced software, CBCT facilitates the visualisation of soft tissue to allow control for post-treatment aesthetics, for example in clef palate cases to evaluate lip and palate bony depressions.2,3,4

Research is underway to assess its ability to detect salivary gland defects.4,24,41 Honda et al.17 describe a clinical case in which the necessity of complete a tooth auto-transplant case was significantly shortened owing to the application of CBCT.

Endodontics

CBCT is a very useful tool in diagnosing apical lesions (Figs. 2a & b).4,5,24,40 A number of studies have demonstrated its ability to detect a false-positive diagnosis of apical lesions by measuring the density from the contrasted images of these lesions, in whether the lesion is an apical granuloma or an apical cyst (Figs. 3a & b).40,41 Cotton et al.40 used CBCT as a tool to assess whether the lesion was endodontic or non-endodontic origin.

CBCT also demonstrated superiority to 2-D radiographs in detecting fractured roots. Vertical and horizontal root fracture detection is described in several clinical cases.2,28,30,31 It is also agreed that CBCT is superior to peri-apical radiographs in detecting these fractures, whether they are bucco-lingual or mesiodistal.2,3,4

In cases with inflammatory root resorption, lesions are detected much easier in early stages with CBCT compared to conventional 2-D X-rays.2,3,4,5,8 In other cases, such as external root resorption, external cervical and internal resorption, not only the presence of resorption was detected, but also the extent of it.2,3,4,5,8,24 CBCT can also be used to determine root morphology, the number of roots, canals and accessory canals, as well as to establishing the working length and angulations of roots and canals.2,28,31,40,41 As key phrases, it is also accurate in assessing root-canal fillings.2,28,31,40 Owing to its accuracy, it is very helpful in detecting the pulpal extensions in talon cusps31 and the position of fractured instruments.40

It is also a reliable tool for pre-surgical assessment of the proximity of the tooth to adjacent vital structures, size and extent of lesions, as well as the anatomy and morphology of roots with very accurate measurements.2,28,31,40,41,43,55,58

Fig. 4b, CBCT images for the same patient. Data obtained from these images regarding bone quality, implant length and diameter, implant location and proximity to vital structures is magnificent.
Implantology

With increased demand for replacing missing teeth with dental implants, accurate measurements are needed to avoid damage to vital structures. This was achievable with conventional CT. However, with CBCT giving more accurate measurements at lower dosages, it is the preferred option in implant dentistry today (Figs. 4a & b).18,26,56,70,80–81,85,88,95–97 With new software that constructs surgical guides, damage is also reduced further.77,84,90–93 Heiland et al.46,55,73–74 describe a technique in which CBCT was used inter-operatively in two cases to navigate the implant insertion following microsurgical bone transfer. CBCT enables the assessment of bone quality and bone quantity.18,26,33,36,57,60,63,83 This leads to reduced implant failure, as case selection can be based on much more reliable information.

Orthodontics

Orthodontists can use CBCT images in orthodontic assessment and cephalometric analysis.18,56,73–74,80–81 Today, CBCT is already the tool of choice in the assessment of facial growth, age, airway function and disturbances in tooth eruption.104–105 CBCT is a reliable tool in the assessment of the proximity to vital structures that may interfere with orthodontic treatment.105–106 In cases in which mini-screw implants are placed to serve as a temporary anchorage, CBCT is useful for ensuring a safe insertion106–108 and to assess the bone density before, during and after treatment (Fig. 6).109–110

Having different views in one scan, such as frontal, right and left lateral, 45-degree views and sub-mental, also adds to the advantages of CBCT.113–116 As the images are self-corrected from the magnification to produce orthogonal images with 1:1 ratio, higher accuracy is ensured. CBCT is thus considered a better option for the clinician.113

Temporomandibular joint disorder

One of the major advantages of CBCT is its ability to define the true position of the condyle in the fossa, which often reveals possible dislocation of the condyle in the joint, and the extent of translational or rotational changes in the joint.105,106 With its accuracy, measurements of the roof of the glenoid fossa can be done easily.113–116 Another advantage of some of the available devices is their ability to visualise soft tissue around the TMJ, which may reduce the need for magnetic resonance imaging in these cases.113

Owing to these advantages, CBCT is the imaging device of choice in cases of trauma, pain, dysfunction, fibro-osseous ankylosis and in detecting condylar cortical erosion and cysts.105,113–116 With the use of the 3-D features, the image-guided puncture technique, which is a treatment modality for TMJ disk adhesion, can safely be performed.113

Periodontics

CBCT can be used in assessing a detailed morphologic description of the bone because it has proved to be accurate with only minimal error margins.112 The measurements proved to be as accurate as direct measurements with a periodontal probe.96–98 Furthermore, it also aids in assessing furcation involving teeth.119–121 CBCT can be used to detect bicuspid and lingual defects, which was previously not possible with conventional 2-D radiographs.122 Additionally, owing to the high accuracy of CBCT measurements, intra-bony defects can accurately be measured and dehiscence, fenestration defects and periodontal cysts assessed.96,106–107 CBCT has also proved its superiority in evaluating the outcome of regenerative periodontal therapy.122

General dentistry

Based on the available literature, CBCT is not justified for use...
in detecting occlusal caries, since the dose is much higher than conventional radiographs with no additional information gained. However, it proved to be useful in assessing proximal caries and its depth.16 Table I shows the representative typical doses of various dental radiological procedures in dental practice.

Forensic dentistry

Many dental diagnostic purposes, which are a key element in forensic science, are described in the literature. CBCT was established as a non-invasive method to estimate the age of a person based on the pulp-tooth ratio.16

Discussion

CBCT scanners represent a great advance in dento-maxillofacial (DMD) imaging technology, introduced into dental use in the late 1990s, and has advanced dentistry significantly. The number of CBCT-related papers published each year has increased extremely in the last years. The above systematic review of the literature - related to CBCT scanners - applications in dental practice was undertaken in order to summarise concisely the literature images of these new imaging techniques in different dental specialties.

The clinical applications for CBCT imaging in dentistry are increasing. The results of this review demonstrate that 154 papers were clinically relevant and that the most common clinical applications are in the field of oral and maxillofacial surgery, implant dentistry, and endodontics. CBCT has limited use in the operator dentistry owing to the high radiation dose required in routine clinical practice.

The literature on CBCT is promising and needs further research, especially with regard to its use in forensic dentistry, in order to explore more potentially beneficial indications in that area. No literature concerning direct CBCT indications in prosthodontics was found. However, several overlapping indications were found in other dental specialties attributing to the final standard of prosthodontic treatment. These indications include but are not limited to bone grafting, soft-tissue grafting, prosthetically driven implant surgery, orthodontics and temporomandibular joint disorder. CBCT can also be of great value in special cases in which multiple teeth have to be assessed for restorability.7-10

The latest CBCT units have a higher resolution, lower exposure, are less expensive and designed for use in dentistry. Additionally, the flat-panel detectors appear to be less prone to beam-hardening artefacts. There are, however, several important disadvantages. As such, suspicion to movement artefacts, low contrast resolution, limited capability to visualise internal soft tissues and, owing to distortion of Housefield Units, CBCT cannot be used for the estimation of bone density. It is crucial that the ALARA principle (As Low As Reasonably Achievable) is respected during treatment, as far as the radiation dose of CBCT imaging is concerned. CBCT imaging will improve patient care, but users have to be trained in order to interpret the scanned data thoroughly. Dentists should ask themselves whether these imaging modalities actually add to the patient’s management.

CBCT should only be used when the question for which imaging is required cannot be answered adequately by lower dose conventional (i.e. traditional) imaging. CBCT is most frequently applied in orthodontics to the floor of the nose (for example, extractions done for teeth #7, 8, 9 and 10 were atraumatic and bone grafting was performed). Furthermore, CBCT images can also be of great value in orthodontic programmes that allow the lowest achievable dose to be used.

References

1. CBCT examinations must not be carried out unless a history and clinical examination have been performed.
2. CBCT examinations must be justified for each patient to demonstrate that the benefits outweigh the risks.
3. CBCT examinations should potentially add new information to aid the patient’s management.
4. CBCT should not be repeated on a patient ‘routinely’ without a new risk/benefit assessment having been performed.
5. When accepting referrals from other dentists for CBCT examinations, the referring dentist must supply sufficient clinical information (results of any radiological examination) to allow the CBCT practitioner to perform the justifi-
cation process.
6. CBCT should only be used when the question for which imaging is required cannot be answered adequately with lower dose conventional (i.e. traditional) imaging. CBCT images must undergo a thorough clinical evaluation (radiological report) of the entire image dataset.
7. Where it is likely that evaluation of soft tissues will be required as part of the patient’s radiological assessment, the appropriate imaging should be conventional medical CT or MR, rather than CBCT.
8. CBCT equipment should offer a choice of resolution, with examinations made more suitable that is compatible with the clinical situation, if this provides a lower radiation dose to the patient.
9. Where CBCT equipment offers a choice of resolution, the resolution compatible with an adequate diagnosis and the lowest achievable dose should be used.
10. A quality assurance programme must be established and implemented for each CBCT facility, including equipment, techniques and quality-control procedures.
11. CBCT equipment should undergo a critical examination and de-
tailed acceptance tests before use to ensure that radiation protection for staff, members of the public and patients is optimal.
12. New installations of CBCT equipment should undergo a critical examination and detailed acceptance tests before use to ensure that radiation protection for staff, members of the public and patients is optimal.
13. CBCT equipment should undergo regular review to ensure that the benefits outweigh the risks.
14. CBCT equipment should undergo a critical examination and detailed acceptance tests before use to ensure that radiation protection for staff, members of the public and patients is optimal.
15. Clinical examinations must use the lowest achievable dose (ALA R A) is respected during treatment.
16. All those involved with CBCT must have received adequate theoretical and practical training for the purpose of radiological practices and relevant competence in radiation protection.
17. Continuing education and training after qualification are required, particularly when new CBCT equipment or techniques are adopted.
18. Dentists responsible for CBCT facilities, who have not previously received ‘adequate theoretical and practical training’, should undergo a period of additional theoretical and practical training that has been validated by an academic institution (university or equivalent). Where national specialist qualifications in dento-maxillofacial radiology exist, the design and delivery of CBCT training programmes should involve a DFM radiologist.
19. For dento-alveolar CBCT images of the teeth, their supporting structures, the mandible and the maxilla up to the floor of the nose (for example, 8 cm × 8 cm or smaller fields of view), clinical evaluation (radiological report) should be done by a specially trained DFM radiologist or by a clinical radiologist (medical radiologist).

Conclusion

CBCT is most frequently applied in orthodontics, dental surgery, endodontics, implant dentistry and orthodontics. CBCT examination must not be carried out unless its medical necessity is proven and the benefits outweigh the risks. Furthermore, CBCT images must undergo thorough clinical evaluation (radiological report) of the entire image dataset in order to maximise the benefits. Future research should focus on accurate data with regard to the radiation dose of these units. CBCT units have small detector sizes and the field of view and scanned volumes are limited, which is the reason that CBCT units specific to orthodontic and orthognathic surgery are not yet available. Additional publications on CBCT indications in forensic dentistry and prosthodontics are also desirable._

Dr Hadi M. Alamri and Dr Maaren A. Alshababah are interns at Riyadh Colleges of Dentistry and Pharmacy.
Removal of a fractured instrument: Two case reports

Author: Dr Rafael Michiels, Belgium

Fractured instruments pose a challenge to every endodontist. The difficulty in the retrieval of these instruments ranges from surprisingly easy to downright impossible. The clinical outcome of cases with fractured instruments depends on several factors, such as the position of the instrument in the canal, the type of material, the instrument size and canal anatomy. Failure in retrieval of the fractured instrument does not automatically result in failure of the case. One can still try to bypass the instrument, choose a surgical approach, or even wait and see. However, if we bear ‘nothing ventured, nothing gained’ in mind, then we should always at least try to retrieve the fractured instrument.

Case I

A 27-year-old female patient was referred to our practice. She was in good health and had an American Society of Anesthesiologists (ASA) score of 1. The patient had some mild clinical symptoms on tooth #30 due to apical periodontitis. She had been told, by the referring dentist, that there was a fractured instrument in her tooth and that the instrument had to be removed first in order to allow for decent retreatment.

Before starting with the treatment, a new diagnostic radiograph was taken. In this case, the diagnostic radiograph (Fig. 1) showed not one but two broken instruments in the mesial root, one in each mesial canal. Thereafter, the tooth was isolated with the rubber dam and the coronal filling was removed. Straight-line access was established, as this is imperative in order to see the fractured instruments.

Gates-Glidden burs (DENTSPLY Maillefer) were used to enlarge the mesial orifices coronally. One-and-a-half hours after starting the treatment, the fragment had been loosened but was still stuck in the canal. We decided to leave it in place for the time being and made a new appointment. Calcium hydroxide paste (UltraCal XS, Ultradent) was put into the coronal part of the mesial canals and the tooth was sealed with glass-ionomer cement (Fuji IX GP Fast, GC) and a cotton pellet.

During the next visit, the tooth was again isolated and opened. The calcium hydroxide paste was removed, using 10 % EDTA.

Fig. 1 Diagnostic radiograph, showing two separated instruments in the mesial root.
Fig. 2 A modified Gates-Glidden bur used for creating a plateau above the instrument.
After five minutes, the fragment in the mesio-buccal canal was removed. Another five minutes later, the instrument in the mesio-lingual canal was also removed. While removing the instrument in the mesio-buccal canal was very time-consuming, removing the instrument from the mesio-lingual canal was surprisingly easy. This clearly highlights the above-mentioned difficulty range of instrument retrieval.

After the removal of both instruments, working length was determined in both mesial canals with the electronic apex locator (Root ZX Mini, Morita). A glide path was established and the mesial canals were initially shaped with a ProTaper S1 (DENTSPLY Maillefer). Smear-layer removal was carried out by irrigating the canal with 10% citric acid. A final wash of the canal was performed with sterile saline. Tapered gutta-percha cones were then fitted (Fig. 4) and tug-back was confirmed. Topseal (DENTSPLY Maillefer) was used as a root-canal sealer. Obturation was performed according to the continuous wave of condensation technique with the Elements Obturation Unit (SybronEndo). After obturation (Fig. 5), a temporary restoration of glass-ionomer cement was placed (Fujifilm IX GP Fast). Final radiographs (Figs. 6 & 7) were taken, both parallel and angled. The radiographs show two completely separated mesial canals; hence, instrument removal in both canals was favourable. The prognosis of this case was good and the patient was referred to her general dentist for a definitive coronal restoration.

**Case II**

A 19-year-old male patient was referred to our practice. He was in good health and had an AAS score of I. The referring dentist had fractured a small instrument—most likely a size 10 or 15 K-file, according to his referral letter—while performing root-canal treatment. Apical finishing was carried out with size 25 K-flex files. Smear-layer removal was performed with a rinse of 10% citric acid. A final wash of the canal was carried out with sterile saline. Tapered gutta-percha cones were then fitted and tug-back was confirmed (Fig. 15).

Topseal was used as a root-canal sealer. Both canals were obturated according to the con-tinuous wave of condensation technique with the Elements Obturation Unit. After obturation (Figs. 14 & 15), a temporary restoration in glass-ionomer cement was placed together with a cotton pellet, which was soaked in an alcohol and chlorhexidine mixture first and then air-dried after it had been placed in the access cavity. Final radiographs (Figs. 16 & 17) were taken, both parallel and angled. The prognosis of this case was good and the patient was referred to his general dentist for a definitive coronal restoration.

**Conclusion**

In the end, removal of a fractured instrument can be very difficult and it may take a long time to accomplish. Dr Marga Rees once said on the ROOTS forum that she was being taught that endodontics is all about the three Ps: Passion, Persistence and Patience. This hits the nail right on the head as far as instrument retrieval is concerned.

Everyone has a shade
And it’s simple to match it

She's an A1B. And, with the improved, lifelike esthetics and “single-shade simplicity” of Filtek™ Z350 XT Universal Restorative, it's the only shade you'll need to restore her beautiful smile.

Simple to use
- Exceptional handling
- More Body shades for single-shade restorations
- Bold, easy-to-read, color-coded labels

Lifelike esthetics
- Excellent polish
- Wide range of shades and opacities
- Improved fluorescence

Unique nanofiller technology
- Better polish retention than a microfill
- Wears better than leading competitors*
- Outstanding strength for anterior and posterior use

Your simple solution for lifelike restorations is Filtek Z350 XT Universal Restorative.
