Two approaches and one goal

State-of-the-art CAD/CAM materials are offering clinicians the possibility of producing certain types of restorations in the dental practice using a semi-direct technique. Ceramic veneers, for example, are easy to fabricate in-office with IPS CAD Multi, without the need for glazing.

By Dr. Eduardo Mahn, Chile

Recently developed restorative materials have opened up a myriad of exciting possibilities for dental practitioners. In the restoration of anterior teeth, clinicians have to select the most appropriate material for the case at hand on the basis of specific criteria. In situations where teeth show signs of erosion, abrasion, attrition or a combination of these phenomena, practitioners will tend towards using ceramics or composite resins, depending on how much intact tooth structure remains available. Traditionally, composites are used for Class III, IV and V defects. However, ceramic veneers are preferred in cases where a large amount of tooth structure is missing or a major change is planned (e.g. smile makeover).

The challenge

When two central incisors need esthetic enhancement, the choice of approach is not so clear. Irrespective of the material used a minimally invasive route involving very little preparation of the tooth structure can be taken nowadays due to the high strength of modern materials (e.g. lithium disilicate or leucite-reinforced ceramics). With the advent of CAD/CAM technology, the possibility of the press and CAD/CAM techniques and the latest improvements of the press and CAD/CAM techniques and the latest improvements of this type of restoration, practitioners will tend towards using ceramics or composite resins, depending on how much intact tooth structure remains available. Traditionally, composites are used for Class III, IV and V defects. However, ceramic veneers are preferred in cases where a large amount of tooth structure is missing or a major change is planned (e.g. smile makeover).

Clinical case

Patient history

A thirty-one-year-old female patient came to our office because she was dissatisfied with her anterior teeth. She complained about the misalignment of the upper and lower central incisors. A detailed clinical examination revealed that the composite restorations in these teeth were defective. As a result of erosion, a considerable amount of tooth structure had been lost. In addition, the misalignment of tooth 31 and 41 in particular was quite obvious. The treatment plan presented to the patient included initial orthodontic treatment followed by minimally invasive orthodontic treatment. Unfortunately, it took more than a year before she presented to the practice again. At this consultation, we were quite surprised to find that the two central incisors had been restored with poorly finished direct composite veneers. The patient was subsequently referred to an orthodontist for treatment. Unfortunately, it took more than a year before she presented to the practice again. At this consultation, we were quite surprised to find that the two central incisors had been restored with poorly finished direct composite veneers.

The treatment

The composite veneers had to be removed and replaced with new ones. In this particular case, the advantages of using the indirect technique were obvious. The patient agreed to have two ceramic veneers made for her. For this purpose impressions were taken and a master cast was produced. This working model provided the dental technician with the opportunity to evaluate the situation in detail. He or she has the time to think about possible ways of correcting the misalignment.

Dentists do not have this "luxury" of time when they are treating a patient in the dental chair. They have to finish the restorations as quickly as possible in order to prevent contamination of the treatment field and keep chair time to a minimum for the comfort of the patient. In the present case, an additional hurdle had to be overcome. Any composite material that might have remained on the tooth structure had to be clearly identified and carefully removed without damaging the healthy tooth structure. Transillumination with white LED light came in
Fabrication of the restorations

Two different routes were pursued in the fabrication of the veneers. We instructed our lab technician to make two ceramic veneers using the press technique with IPS e.max® Press (shade HT A1, stained). At the same time, we milled two ceramic veneers with our in-office CAD/CAM machine using an IPS Empress CAD Multi block (shade A1). The veneers made in the dental office were not glazed, just polished. Figures 6 and 7 allow the results to be compared from a facial perspective. This experiment illustrates the aesthetic potential of modern ceramics. Both types of restorations blend in beautifully with their surroundings.

The appearance of the veneers produced with the help of CAD/CAM technology came very close to that of the manually manufactured version. Nevertheless, in the end we opted for the lab-fabricated veneers (IPS e.max Press) with the consent of the patient, since we were able to achieve a slightly better match to the neighbouring teeth by staining the restorations.

Placement

Figures 8 and 9 show the try-in pastes (Variolink Esthetic LC) on the prepared teeth. The most suitable composite cement was determined on the basis of two differently coloured pastes. Two extreme options were compared: Lights+ and Warn+. The difference was clearly visible when the pastes were applied. Even though the darker shade (Warn+) was very close to that of the natural tooth structure and would have worked well with the veneers, we ended up choosing the lighter shade. This was a typical decision. In most cases, we tend to prefer the lighter version, since it provides a better contrast to the tooth structure and therefore renders the removal of excess cement easier and faster. Before the veneers were seated, retraction cords were placed and the enamel was etched; the dentin remained unetched. Adhese® Universal was used as the bonding agent to place the veneers (Figs 10 and 11). Then the excess luting composite was carefully removed and a glycerine gel (Liquid Strip) was applied (Fig. 12). This gel prevents the formation of an oxygen inhibition layer at the margins. The luting composite was cured with two curing lights (Bluephase® Style) simultaneously and cooled with plenty of water (Fig. 13). Figure 14 shows the harmonious result produced by the lithium disilicate veneers.

Conclusion

State-of-the-art restorative materials have immense potential. Depending on the particular requirements of the patient and the indication, they allow a suitable treatment option to be found quickly and easily. The case presented here shows that highly aesthetic ceramic veneers can be fabricated with minimal effort using in-office equipment (IPS Empress CAD). Nevertheless, pressed ceramic veneers were chosen for this patient, since they offered the possibility of applying stains, through which a very close match to the neighbouring teeth could be attained. In principle, however, highly aesthetic results can be achieved with both approaches if the appropriate treatment protocol is followed.

Intraoral Device for the treatment of Sleep Apnea

By Dr. Luis Gavin, Spain

Bad sleep is the new hokeypokey, threatening the overstimulated, overworked masses with disease and even an early death. Numerous scientific studies from researchers around the world have demonstrated the harmful effects of sleep deprivation on human health. When stress levels go up, people gain weight and forget things. Without shut-eye, the body doesn’t have a chance to produce enough growth hormones to build itself back up.

Sleep Apnea (SA) is a disorder that causes pauses in breathing during sleep that expose the heart to oxygen deprivation. It is common in patients with heart failure (HF) where it is associated with increased risk of hospitalizations and death.

In the treatment of snoring and sleep-disordered breathing the mandibular repositioning devices are an increasingly important instrument.

Its mechanism is based on the advancement of the mandible, which increases the dimensions of the upper airways and the air flow during sleep. Aim of this study was the investigation of the efficiency during sleep. Aim of this study was the investigation of the efficiency during sleep. The OSA Syndrome (obstructive sleep apnea syndrome) is one of the clinical pictures that play an important role in the chronic diseases. It has been demonstrated that a timely diagnosis and an adequate treatment can decrease neurological consequences and have a favorable effect on the cardiovascular health status of affected patients. Clinically it consists in the obstruction of the air flow during sleep that is caused by a partial or total collapse of the upper airway structures. These respiratory obstructions are accompanied by “snoring” and frequent arousals.

Patient have a number of symptoms: daytime sleepiness and fatigue, due to a restless sleep, morning headache, loss of intellectual capacities and nighttime micturition. Sleep apnea affects approximately 7% of the adult population, but the problem may be underestimated, due to the growing global prevalence of obesity. For decades the continuous positive airway pressure (CPAP) mask has been the treatment of choice, but its disadvantages, rejection and intolerance on part of the patients complicate the option of choice, but its’ disadvantages, rejection and intolerance on part of the patients complicate the treatment solutions by an easy and immediate therapeutic way. These systems underwent technological developments in the last years the treatments of choice for patients who suffer from with snoring and mild or moderate sleep apnea.

Why is important the treatment of snoring and sleep apnea? Importance is based on the following reasons:

1. High prevalence in today’s society, as various studies have demonstrated in the last years. There exists an incidence of 25% for snoring, approximately 40% of adults more frequently and 35% habitually. The prevalence of OSA ranges from 6-8% in males and 4-6% in women among the general adult, middle aged population and this numbers increase markedly with age.

2. It represents a problem in two aspects, the social that converts these patients in intolerable bed partners and the more serious clinical impact of significant morbidity. These impacts can reach a noise level of about 78-88dB (equal to the noise of a truck at high speed on a highway). The limit for hearing damages is estimated at an intensity of 75 dB. Snoring disturbs social and family relationships of patients. Its psychological pressure influences both lives, the daily routine of people who snore, as well as the every day life of people, who

Introduction
The OSA Syndrome (obstructive sleep apnea syndrome) is one of the clinical pictures that play an important role in the chronic diseases. It has been demonstrated that a timely diagnosis and an adequate treatment can decrease neurological consequences and have a favorable effect on the cardiovascular health status of affected patients. Clinically it consists in the obstruction of the air flow during sleep that is caused by a partial or total collapse of the upper airway structures. These respiratory obstructions are accompanied by “snoring” and frequent arousals.

Patient have a number of symptoms: daytime sleepiness and fatigue, due to a restless sleep, morning headache, loss of intellectual capacities and nighttime micturition. Sleep apnea affects approximately 7% of the adult population, but the problem may be underestimated, due to the growing global prevalence of obesity. For decades the continuous positive airway pressure (CPAP) mask has been the treatment of choice, but its disadvantages, rejection and intolerance on part of the patients complicate the treatment solutions by an easy and immediate therapeutic way. These systems underwent technological developments in the last years the treatments of choice for patients who suffer from with snoring and mild or moderate sleep apnea.

Why is important the treatment of snoring and sleep apnea? Importance is based on the following reasons:

1. High prevalence in today’s society, as various studies have demonstrated in the last years. There exists an incidence of 25% for snoring, approximately 40% of adults more frequently and 35% habitually. The prevalence of OSA ranges from 6-8% in males and 4-6% in women among the general adult, middle aged population and this numbers increase markedly with age.

2. It represents a problem in two aspects, the social that converts these patients in intolerable bed partners and the more serious clinical impact of significant morbidity. These impacts can reach a noise level of about 78-88dB (equal to the noise of a truck at high speed on a highway). The limit for hearing damages is estimated at an intensity of 75 dB. Snoring disturbs social and family relationships of patients. Its psychological pressure influences both lives, the daily routine of people who snore, as well as the every day life of people, who

suffer from the noisy consequences causing problems in the partnerships.
3. Disordered breathing by sleep is very habitual and, therefore, a constant source of problems regarding health and economic impacts. Poor sleep habits aggravate the impairments of health and quality of life causing countless traffic accidents, fatal accidents and accidental home injuries. The majority of these disorders lead to difficulties in their clinical description, disabling affected patients to drive. In all countries the number of fatal accidents increases constantly.
It is the first cause in men aged between 25 and 35.
4. The access to diagnosis possibilities is the major problem facing the specialists, as only about 6 to 7% of the population with relevant OSA is diagnosed. Clinical researchers seek for diagnostic alternatives to the costly polysomnography that is currently the first diagnosis confirmation (6). The OSA is rarely known to the public. The lack of diagnosis is the main problem to solve. Recent studies show that in only 7% of medical examinations of primary care, explicit references regarding possible sleep disorders are included. This incorrect diagnosis involves fatal consequences because the pathology is ignored by patients that, without being diagnosed, do not know how to justify and cope with the symptoms that they face day by day.

To conclude, school and work absence and the reduced capacity at work also cause economic damages.

**Objectives and hypotheses**

Hypothyroidism

Hypothyroidism is an endocrine disorder characterized by a decrease in the production of thyroid hormones. The primary cause is autoimmune thyroiditis, which primarily affects the thyroid gland, leading to a reduction in the production of thyroid hormones. Hypothyroidism has a significant impact on overall health and can lead to various symptoms, including fatigue, weight gain, depression, and cognitive impairment.

### Methodology

**Description and subject group selection**

The study group consists of 30 snoring adults, with mild to moderate sleep apnea, aged between 16 and 25 years, 8 women and 22 men, who were treated with a mandibular advancement device (MAD).

A complete dental examination was performed to get more detailed information about TMD and dental and bone structure. It included peri-odontal and dental examination, panoramic radiography and lateral cephalometry, evaluation of the tongue and soft tissues and finally, possible occlusion defects.

**Inclusion Criteria**

- Snorers
- The patient should have the ability to advance the mandible forward and open it without significant limitations.

**Exclusion Criteria**

- Patients with severe OSAS
- Patients with rhinopharyngeal pathology
- Inappropriate dentition, peri-odontal diseases without treatment
- Serious problems in the temporomandibular joint (TMD)
- Insufficient protrusion capacity

**Conclusion**

- This study supports the use of MAD in the treatment of adult patients.
- It is recommended to use MAD as a first-line treatment for sleep apnea, especially in patients who cannot tolerate CPAP.
- Further research is needed to evaluate the long-term effectiveness and safety of MAD therapy.
