Midline diastema closure with direct-bonding restorations

By Dr. Sushil Koirala, Thailand

Midline diastemata (MD) are spaces of varying magnitude between the crowns of fully erupted maxillary and mandibular central incisors. Kerene describes MD as anterior midline spacing greater than 0.5 mm between the proximal surfaces of adjacent teeth. Incidences of maxillary and mandibular MD are 14.8 and 1.6 %, respectively. MD can occur in temporary, mixed or permanent dentition and may be considered normal for many children during the eruption of the permanent maxillary central incisors. When incisors first erupt, they may be separated by bone and the crowns incline distally because of the crowding of the roots. With the eruption of the laterals and permanent canines, the MD reduces or even closes completely.

Etiological factors

The etiological factors of MD are described by various researchers. Angle concludes the presence of an abnormal frenum to be the cause of MD/a view that has been supported by other researchers. According to Tait, the frenum is the effect and not the cause of the incidence of diastemata. He reports causes such as ankylosed central incisors, flared or rotated central incisors, anodontia, macroglossia, dental-alvolar disproportion, localised spacing, closed bite, facial type, ethnic and genetic characteristics, inter-precimal suture and midline pathology. Weber lists the causes for spacing between maxillary incisors as the result of high frenum attachment, microdontia, macrognathia, supernumerary teeth, peg laterals, missing lateral incisors, midline cysts, habits such as thumb sucking, mouth breathing and tongue thrusting.

Therefore, the etiological factors can be summarised as follows:

1. developmental: microdontia, missing laterals, mesiodens, macrognathia, macro hypertrophic fibrous frenum;
2. pathological: midline cysts, tumours and periodontitis;
3. neuromuscular: oral habits, such as tongue thrusting during speech, swallowing or abnormal pressure during rest.

Clinicians must be prepared for patients visiting the dental office with the aim of having their diastema closed in order to fulfil their psychological (aesthetic and beauty enhancement), functional (pronunciation of ‘f’ and ‘s’ sounds and cutting foods with anterior teeth) and/or health (oral health maintenance) problems.

Treatment options for diastema closure

Treatment modalities depend on the etiological factors and complexity of the MD. It is suggested that treatment of a MD should be delayed until the eruption of the permanent canines. However, the pathological causes should be ruled out and treated at an early stage, for example extraction of supernumerary teeth (mesiodens) and surgical treatment for the removal of midline cyst, tumour and periodontal pathologies. Surgical, orthodontic (comprehensive/short term), periodontal, direct bonding and indirect restorations are the treatment modalities that can be used alone or in combination to achieve harmony in terms of a patient’s aesthetics, function and health.

MICD by definition is “a holistic approach that explores the smile defects and aesthetic desires of a patient at an early stage and treats them using the least intervention options in diagnosis, treatment and maintenance technology by considering the psychology, health, function and aesthetics of the patient.” The MICD concept as the professional movement that encourages all clinicians to select diagnosis, treatment and maintenance modalities that are the least invasive in order to preserve healthy oral issues while still achieving the natural aesthetics outcome in the best interests of the patient’s health and happiness.

Following, I will demonstrate the clinical use of MICD TP (minimally invasive cosmetic dentistry treatment protocol) to close or reduce the diastema in clinical practice (Fig. 1). The direct-bonding procedure with the application of the Flowable Frame Technique (FFT) is presented here as a special technique.

Case presentation

A 20-year-old female patient presented with the complaint that she did not like her smile because of the large gap between her upper front teeth. The patient was very concerned about her smile aesthetics and also aware of her speech difficulties.

Phase I: Understand

In the first step of Phase I, the patient’s perception, lifestyle, personality, and desires were explored in a personal interview and through completion of the MICD self smile-evaluation form. The patient, who exhibited a high dental IQ, evaluated her smile as below satisfactory.

After the interview, the disease, force element and aesthetic defects of her smile were explored.

Case presentation

A 20-year-old female patient presented with the complaint that she did not like her smile because of the large gap between her upper front teeth. The patient was very concerned about her smile aesthetics and also aware of her speech difficulties. The patient’s perception, lifestyle, personality, and desires were explored in a personal interview and through completion of the MICD self smile-evaluation form. The patient, who exhibited a high dental IQ, evaluated her smile as below satisfactory.
In the design step, a new smile and lacked central dominance. The tooth-size ratio of the centrals was nearly 65% #12 and 21. The tooth-size ratio of the study model revealed attachment and the space analysis. We found a high frenum as to gain an overview of the agnostic information, such as the patient had good oral health, normal diseases, force elements and gingival health.

The collected clinical and diagnostic information, such as extra and intra-oral digital photographs, study models and x-rays, was further analysed to determine her smile aesthetic grading in terms of her health, function and aesthetics, as well as to gain an overview of the clinical problems and the macro-, micro- and mouth-smile defects. We found a high frenum attachment and the space analysis of the study model revealed a MD of 5.5 mm between teeth #12 and 21. The tooth-size ratio of the centrals was nearly 65% and lacked central dominance.

In the design step, a new smile clinically. Necessary digital photographs were taken, along with diagnostic study models for further exploration of existing diseases, force elements and aesthetic defects. The patient had good oral health, normal function and no para-functional or other destructive oral habits.

The new smile was proposed through the modified digital photographs and aesthetic mock-up of the study model. In order to correct her MD, a frenectomy with non-invasive indirect partial veneers was proposed as the first option and a direct-bonding restoration without frenectomy as the second option. However, because of financial constraints, the patient preferred the second option.

All patient queries related to the proposed new smile and treatment modalities were addressed in detail. The informed consent form was signed prior to proceeding to Phase II.

Phase II: Achieve

In the first step, the patient's health, function and a healthy lifestyle were established. The patient's smile was graded as Grade B. The established parameters of her oral health and function were within normal limits, the aesthetic parameters were below the accepted level and enhancement treatment was to improve her aesthetic parameters further. Hence, in this case, it was not necessary to undergo enhancement treatment (like orthodontic, periodontal, occlusal adjustments, etc.) before proceeding to the aesthetic enhancement step. According to MICD TP, the desire of the patient in this case was need-based or naturo-esthetic smile enhancement.

Direct-bonding restoration

The direct-bonding restoration technique represents the preferred therapeutic option in MICD II preserves maximal tooth structure and helps to restore function and aesthetics in only root conduct. In addition, the technique is economical and the possible need for so-phisticated indirect restoration can be postponed. Direct-bonding restorations demand excellent clinical skills. The clinician is required to incorporate various clinical techniques, tips and tricks. Following, I would like to demonstrate a simple technique that I have applied since 2005 in various clinical scenarios and find helpful for the upgrade of clinicians' restorative skills.

The Flowable Frame Technique

The FFT is a simple restorative technique developed to speed up the placement and simplified confinement of material when restoring challenging anterior aesthetic cases such as large Class IV or Class III defects and diastema closure or reduction. As the name suggests, this technique requires flowable composite resin as frame material, a plastic strip, composite brush and other usual instruments for direct resin restorations.

Clinical steps in the Flowable Frame Technique

The following steps are to be taken:

Step 1
After the completion of etching, priming and bonding of the tooth surfaces, insert a simple plastic strip to the level of gingival sulcus of the tooth to be restored (Fig. 2).

Step 2
Support the plastic matrix strip lingually with your index finger to create a lingual contour (Fig. 3).

Step 3
Inject the flowable composite resin between strip and tooth surface. (either opaques or translucent) and smooth it to a thin layer with a brush or a composite brush if necessary (Fig. 4).

Step 4
Light cure the flowable composite and remove the plastic strip. A flowable frame is now ready (Figs. 5 & 6). The thickness, shape and thickness of the flowable frame can be adjusted using the sharp edge of the hand instrument or a diamond point (Fig. 7).

The advantages of the FFT are:
- time and cost saving (no direct or indirect mockup required);
- thickness of the layer of restoring materials (dentine, enamel and opaques) can be precisely controlled;
- as with the silicone template method, an ovoid halo, material free areas in the proximal and incisal areas can be created;
- smooth, polished surface is achieved with minimal finishing;
- smooth adaptation of the restorations can be achieved even in the gingival sulcus;
- it is the most suitable lingual frame creation technique for diastema reduction or closure.

Material selection and clinical steps for diastema closure

Material selection for diastema closure should be guided by optical properties (light transmissi and diffusion characteristics) and tissue responses of the materials (restoration in diastema normally touches the gingival tissue and sulcus). Amongst the various materials available, gioners are amongst the latest category of micro-hybrid or hybrid lighcured restorative materials and are touted as the true hybrid between traditional ionomers and composite resins. They have the fluoride release and release of glass ionomers and the aesthetics (shade, polish and optical properties), handling and physical properties of composite resins. Gioner restorative and adhesive systems have good bio-compatibility and have been reported not to result in long-term post operative sensitivity.

They have also been found to possess anti-plaque formation properties. Hence, gioner direct-restorative materials and adhesive systems were selected to close the MD in this case.

Beautiful Flow Shade #AT1 with gioner adhesive system FLBond II (SHOFU Inc.) were used in FFT to create the lingual frame. Beautiful Flow II (SHOFU Inc.) dentine shade A1 and enamel shade #12 (either opaques or translucent) were used to restore the defects using the bi-layered shading technique to achieve the desired aesthetics with an invisible restoration. The Direct Cosmetic Restoration Kit and the Super-Snap Rainbow Technique Kit (both SHOFU Inc.) were used to prepare the teeth and polish the final restorations (Figs. 7–22).

Conclusion

Diastema closure or reduction in clinical practice requires detailed case analysis. The success of the treatment depends on etiological factors, size and extent of the diastema, and the patient's affordability in terms of treatment time and costs involved. The MICD TP guides the clinician and the patient and helps both to understand, plan and complete the clinical case using diagnostic and treatment modalities that are the least invasive in order to preserve sound tooth structure and achieve natural aesthetics considering the patient's best needs.

Phase I: Keep in touch

After completion of the treatment, the importance and role of the keep-in-touch concept in the long-term success of aesthetic enhancement procedures were briefly explained to the patient. She was advised to monitor her normal oral hygiene procedures and shown how to keep the interpupillary distance of the diastema clean. In the final step of MICD TP, the patient was requested to fill out the MICD clinical evaluation form. The patient evaluated her new smile as excellent and mentioned that she was fully satisfied with the overall experience and outcome at our centre. The MICD summary table (Table 1) helps to evaluate the overall success of the case.
