Fixed and Removable Implant Restorations: A Solution for Every Arch

By Dr. Paresh B. Patel, USA

When a patient presents with an edentulous arch or terminal dentition, implant treatment can be provided that improves not only form and function, but also quality of life. For patients desiring better chewing capability, stability, esthetics and comfort than a traditional denture can offer, both removable and fixed implant restorations are superior alternatives. While the appropriate implant solution can vary depending on the patient’s oral health, anatomy, quality and quantity of bone, and financial resources, full-arch prosthetics have progressed to the point where virtually every patient can be restored. Although fixed, implant-supported restorations offer the highest levels of stability, function and patient satisfaction, removable overdentures are a dramatic improvement over conventional complete dentures as well. Both treatment options effectively mitigate the bone resorption that occurs following the loss of teeth, helping to preserve the oral and facial structures and, by extension, the self-confidence of the fully edentulous patient. Determining which solution is appropriate requires a careful evaluation of the individual patient’s circumstances and desires. Even when an implant overdenture is delivered, the prosthesis can eventually be converted to a fixed restoration.

As evidenced by the case that follows, in which one arch is restored with an implant overdenture and the other with a BruxZir® Full-Arch Implant Prosthesis, practitioners today have a great deal of clinical flexibility. Whatever prosthetic approach is adopted, immediate, life-changing relief can be provided to patients suffering from terminal dentition or an uncomfortable, poorly functioning traditional denture. Further, the dramatic overhaul of this patient’s oral health demonstrates the life-changing capabilities of implant therapy, which helped him overcome severe functional and esthetic challenges that were impacting practically every facet of his life prior to treatment.

Case Presentation
A 47-year-old male presented with terminal dentition in both arches resulting from periodontal disease and severe caries (Figs. 1a–1c). The patient had already lost many of his teeth, and the dentition that remained had been rendered unstable by his periodontal condition (Fig. 2). He had saved up enough money for a fixed implant restoration for his upper arch, for which he desired the most functional, lifelike prosthesis possible. While he couldn’t afford such a restoration for both arches, he wanted a retentive appliance for his mandible, with the option of later upgrading to a fixed prosthesis. The patient accepted a treatment plan in which his maxilla would be restored with a BruxZir Full-Arch Implant Prosthesis and his mandible with an Inclusive® Locator Implant Overdenture. Fabricating his mandibular restoration from monolithic zirconia would ensure maximum long-term durability. This was important provided the relatively young age of the patient, who would not have to worry about his upper prosthesis succumbing to fractures, chips or stains.

His lower appliance would be held in place by connecting to the implants via Locator® attachments (Zest Anchors, Escondido, Calif.), which are an economical means of improving prosthetic retention and stability. The overdenture caps that connect to the Locator attachments would be incorporated in the prosthesis chairside, though it should be noted that many clinicians elect to have the laboratory handle this step. The surgical phase of treatment called for the extraction of the patient’s remaining teeth followed by

Figures 2, 3, 5, 6, 7a, 7b, 9a, 9b, 9c, 10: Note the dramatic change in appearance of the patient, who left with chairside-converted dentures in place on the same day as surgery, including a screw-retained, fixed provisional for his upper arch.

Figures 8a, 8b: Note the dramatic change in the appearance of the patient, who left with chairside-converted dentures in place on the same day as surgery, including a screw-retained, fixed provisional for his upper arch.

Figures 8a–8c: Preoperative condition of the patient. Note the high lip line, severe cervical decay present on the patient’s remaining teeth, and lack of gingival support.

Figure 3: Maxillary implants with parallel pins in place exhibit the axial placement of the anterior implants and the tilted angulation of the posterior implants.

Figure 4a–4c: The inclusive tapered implants were threaded into place, achieving excellent initial stability.

Figure 5: Multi-unit abutment with carrier in place illustrates connection of the implant’s angulation to establish a uniform prosthetic platform around the arch.

Figure 6: Traditional dentures were fabricated in advance of the surgical appointment so they could be immediately converted to serve as temporary appliances during the healing phase.

Figure 7a, 7b: Same-day conversion of the maxillary denture to an immediate fixed prosthesis was achieved by adding multi-unit temporary cylinders using cold-cure acrylic and trimming the appliance into a horseshoe shape.

Figure 8a, 8b: Note the dramatic change in the appearance of the patient, who left with chairside-converted dentures in place on the same day as surgery, including a screw-retained, fixed provisional for his upper arch.

Figure 9: Postoperative panoramic radiograph illustrates All-on-4 configuration of maxillary implants and axial placement of the mandibular implants, which would facilitate a passive fit of the lower overdenture. Note the temporary cylinders attaching the provisional maxillary denture to the implants.
the immediate placement of eight dental implants. CBCT scans were taken to help determine the optimal placement of the implants within the available bone and away from the patient’s vital oral anatomy. Evaluation of the CBCT scan determined that there was sufficient height, width, and quantity of bone to place the implants in the appropriate locations and angulations via fresh-end surgery. Four 4-mm Inclusive® tapered implants (Glidewell Direct, Irvine, Calif.) would be placed in each arch to support the fixed maxillary restoration and the removable mandibular prosthesis.

At the surgical appointment, the patient’s remaining teeth were removed, and a flap was raised to visualize the socket sites and areas of implantation. Bone leveling was performed on the patient’s maxillary arch to elevate the patient’s smile transition line above the upper lip. The maxillary osteotomies were positioned to facilitate an All-on-4 configuration, with the posterior implants tilted to maximize the anterior-posterior spread. The patient’s bone limitations (Fig. 3) osteotomies were created for the placement of four mandibular implants, as opposed to the minimum of two required for a Locator overdenture. This would enhance retention of the overdenture and minimize the cantilevers and the forces transmitted to the implants during healing. It would also satisfy the patient’s desire to have a fixed, fully functional maxillary prosthesis in place. Note that the two distal-most molars were removed to minimize the cantilevers and the force transmitted to the implants during osseointegration. Healing abutments were placed in the mandibular implants to begin developing the transmucosal passages. The lower immediate denture was then modified and relined to seat over the implants during healing. This approach provided the patient with same-day temporary restorations, and he walked out of the office with properly functioning teeth.

Following creation of the osteotomies, the implants were placed (Figs. 4a–4e). Inclusive® Multi-Unit Abutments (Glidewell Direct) were attached to the maxillary implants, correcting for the divergent angulations of the implants. This would both position the restorative platform in a manner that would situate the screw access holes of the eventual prosthesis toward the lingual aspect and allow for a molar-to-molar restoration (Fig. 5). Note that when patients present for treatment with terminal dentition, they are commonly anxious about losing their teeth and the effect this will have on their speech and chewing capabilities. For this reason, it is important to make every effort to ensure that the patient leaves with functional appliances in place. Thus, traditional dentures were fabricated from preliminary impressions in advance of the surgical appointment for modification and delivery following placement of the implants (Fig. 6).

Having achieved sufficient primary stability, the Inclusive Tapered Implants placed in the patient’s maxilla could be immediately loaded. Thus, the upper denture was trimmed and modified chaussie to connect to the multi-unit abutments through temporary cylinders (Figs. 7a, 7b). This would satisfy the patient’s desire to leave the surgical appointment with a fixed, fully functional maxillary prosthesis in place. Note that the two distal-most molars were removed to minimize the cantilevers and the force transmitted to the implants during osseointegration. Healing abutments were placed in the mandibular implants to begin developing the transmucosal passages. The lower immediate denture was then modified and relined to seat over the implants during healing. This approach provided the patient with same-day temporary restorations, and he walked out of the office with properly functioning teeth for the first time in many years. The effect this had on the patient’s comfort, function, and appearance was immediate and profound (Figs. 8a, 8b). The final radiograph taken after seating the temporary appliances confirmed excellent positioning of the implants (Fig. 9).

At the next appointment, the wax rim was designed to seat over the Locator overdenture while affording the possibility of upgrading to a fixed restoration and the removable mandibular prosthesis. This would enhance retention of the overdenture and minimize the cantilevers and the forces transmitted to the implants during healing.

Removal of the temporary appliances revealed excellent tissue health around the healing abutments of the mandibular and multi-unit abutments of the maxilla (Figs. 10a, 10b). Vinyl polysiloxane (VPS) impressions were taken to begin the restorative process (Figs. 11a–11c). Because multi-unit abutments and healing abutments were placed on the day of surgery, the restorative process began above the tissue level, without any need for secondary surgery or anesthetization.

The restorative protocol for both prostheses included wax rims and setups, which the lab produced on the working casts fabricated from the impressions (Figs. 12a, 12b). The maxillary wax rim incorporated temporary cylinders through which the screws could connect to the dental implants. The lower wax rim was designed to seat over Locator attachments and keep the appliance in place during function. A new master cast of the maxilla was produced based on the custom open-tray final impression. The new master cast and final-approved wax setup were scanned. A virtual model was generated upon which the fixed monolithic prosthesis was designed using CAD software (Figs. 13a, 13b). Because this digital model was based on the final impression containing the verification jig, screw access holes were created in precise alignment with the positions of the maxillary implants.

The CAD design was used to mill a provisional implant prosthesis from polymeric methylmethacrylate (PMMA) (Figs. 20a, 20b). This appliance was tried in and worn for a trial period, thus ensuring an accurate prosthetic design. The provisional implant prosthesis is an essential element of the restorative process, as significant adjustments cannot be made to the final restoration once it has been milled from BruxZir Solid Zirconia.

At the following appointment, the Inclusive Tapered Implants overdenture was seated and checked for proper fit, function, and support from the soft tissue. The provisional implant prosthesis was screwed into place, and its teeth positioning, function and esthetics were verified (Figs. 21a, 21b). With both appliances in place, the interocclusal...
relationship was checked (Figs. 22a, 22b). Minor occlusal adjustments were made directly to the maxillary provisional implant prosthesis, as PMMA is easily modified. Slight alterations were also made to the lower implant overdenture. Then, blockout shims and the retentive overdenture caps were seated over the Locator attachments (Figs. 23a, 23b). Quick Up self-cure material (VOCC America, Indiana, IN) was added to the recess wells of the overdenture caps and recess wells of the prosthesis. NOTE: In many cases, the doctor elects to have the overdenture caps processed by the lab.

Figures 17a–17c: The individual sections of the implant verification jig were seated and luted together before being picked up in the open-tray final impression, which was made using a custom tray and Capture® VPS material (Glidewell Direct).

Figures 18a, 18b: The final lower implant overdenture was designed to seat over Locator attachment analogs situated in the mandibular cast. This would allow the overdenture caps that engage the Locator attachments to be picked up chairside. Figures 19a, 19b: Diagram software was designed to draw the definitive prosthesis for the patient's maxilla based on the final impression and approved wax-up setup. Some access holes were created in the precise positions needed for a passive fit.

Figures 20a, 20b: The provisional implant prosthesis was milled and seated on the master cast to verify a proper fit as well as the interocclusal relationship with the opposing implant overdenture.

Figures 21a, 21b: After seating the final lower implant overdenture, the maxillary provisional implant prosthesis was tried in to verify fit, form and function.

Figures 22a, 22b: The definitive maxillary restoration was milled from BruxZir® Solid Zirconia, incorporating the slight adjustments that were made to the PMMA provisional appliance.

Figures 23a, 23b: The metal housings of the overdenture caps were seated over the Locator attachments.

Figures 24, 25: The definitive maxillary restoration was milled from BruxZir® Solid Zirconia, incorporating the slight adjustments that were made to the PMMA provisional appliance.

Figures 26: Patient with the final Locator overdenture.

Figures 27: The definitive maxillary restoration was milled from BruxZir® Solid Zirconia, incorporating the slight adjustments that were made to the PMMA provisional appliance.

Figures 28a, 28b: The definitive BruxZir® Full-Arch Implant Prosthesis completed a dramatic oral reconstruction for a patient who presented with terminal dentition, entraining form, function and quality of life.

S.C.) was added to the recess wells of the overdenture before seating the appliance over the metal housings. After letting the material set for approximately three minutes, the overdenture was removed, picking up the denture caps in the prosthesis. The minor voids surrounding the denture caps were then filled with Quick Up light-cured pink composite (Fig. 24). The appropriate retentive inserts, which are available in a variety of strengths depending on the functional capabilities of the patient and the number of implants, were swapped into the metal housings (Fig. 25). The implant overdenture was reseated, providing excellent retention, stability and function for the patient. With the final mandibular restoration in place, the patient wore the provisional full-arch implant prosthesis for a trial period of two weeks (Fig. 26). This opportunity to wear the appliance during actual day-to-day function instilled a high degree of confidence in the prosthetic design for the patient and doctor alike. Following patient approval, the provisional implant prosthesis was returned to the lab so it could serve as the blueprint for the final restoration and the minor adjustments made to the appliance could be included in the definitive prosthetic design. The final BruxZir® Full-Arch Implant Prosthesis was digitally fabricated with precision (Fig. 27). As an exact reproduction of the test-driven prosthesis, the definitive prosthesis fit perfectly and offered the esthetics and function the patient had come to expect (Figs. 28a, 28b). The final restoration effectively addressed the unique circumstances of the case, providing the most durable, stable prosthesis possible for his upper, and a lower restoration that greatly improves prosthetic retention and can be upgraded to a fixed prosthesis should the patient’s situation change.

Conclusion
Practitioners now have the clinical flexibility to offer patients a wide range of treatment options, from entry-level, economical restorations like the Inclusive Locator Implant Overdenture, to the fixed, highly durable BruxZir® Full-Arch Implant Prosthesis. There is a viable means of treating nearly all patients, whatever their oral health, needs and finances. Provided the life-changing benefits of implant therapy and the straightforward restorative protocols of today, this service should be offered to all patients confronting the challenges presented by complete edentulism.
